Page theme

The product of radiation on Mammoth sunflowers, Tower Flowers are aptly named for their height. Still edible to humans and animals, it's water consumption has stopped it from being widely cultivated.

Biology

Tower Flowers are the result of several mutations of Mammoth Sunflowers due to the radioactive sediment from the Great War and Black Rain. One of the affected genes was the one responsible for growth, and many plants grew even taller in the generations after the War. The stems were forced to grow as a result, and it is not uncommon to see a flower bowing over as its head grows faster than the stem.

The petals of the plant grew smaller over time, though are still relatively large given the size of the plant. The root network has also changed, now able to burrow deeper in pursuit of water, which Tower Flowers consume at a rapid rate.

Properties

Tower Flowers are best known for their growth, as they can easily reach full height from germination in eight weeks. A

side effect of this rapid growth is it's water consumption, with a single plant able to consume four gallons a day in the summer.

Uses

Food, Oil

The plant still possesses edible seeds, with a single plant averaging four pounds of seeds when mature. The petals of the Tower Flower can still be mashed with the fan leaves for oil, though it has developed a more bitter taste than it's forebearer. The stem of the plant has limited use besides animal feed, and while tribals and low-resource wasters sometimes use them as poles or handles, the stems will either and decay relatively quickly unless treated.

Habitat

Tower Flowers can be found throughout North America, though grow best in sunny, wet climates. The type of soil has little effect on the plant, unless radioactive sediment is present, in which case it'll stunt the plant's growth.
